

## Köhler Illumination & Phase Contrast Alignment on the Nikon Ti2

Focus on Sample – Set condenser turret to empty brightfield position, remove all other filters and prisms from light path, and fully open field and aperture diaphragms. Use the focus knob to bring the sample into focus.

Open the Field Diaphragm – Once open, the edges should extend just past the desired field of view. Fine centration of field diaphragm may be performed while mostly (but not fully) opened.

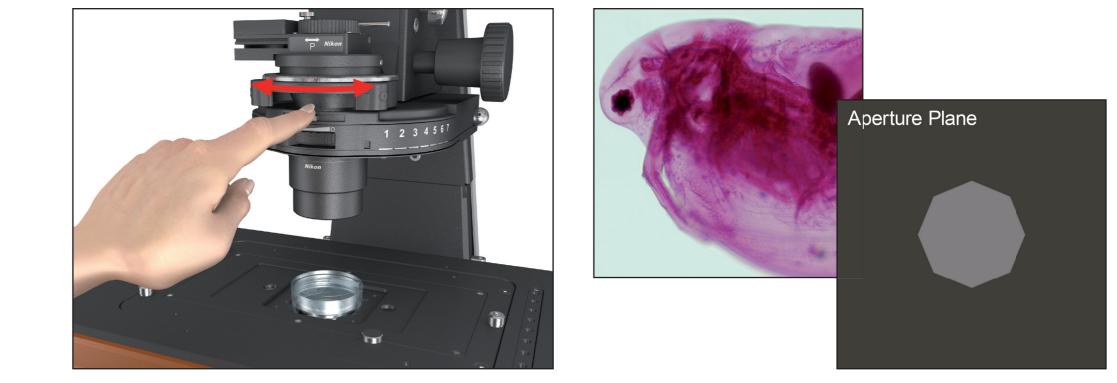

Aperture Plane
Aperture Plane

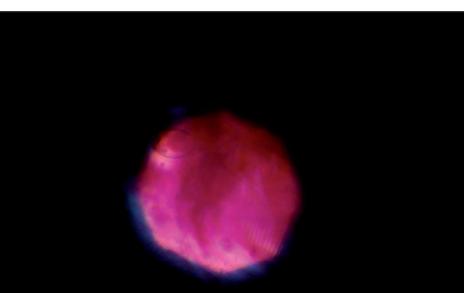

**Close Field Diaphragm** – Once closed, the out-of-focus image of the field diaphragm should be somewhat visible within the field of view.

Visualize Back Aperture – Insert Bertrand Lens into light path by rotating illustrated knob (a). Focus on edges of back aperture using smaller internal knob (b).

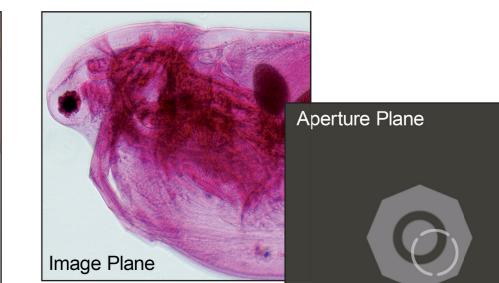

Adjust Condenser Aperture Diaphragm – The aperture diaphragm should be closed until its image fills about 70% of the back aperture.

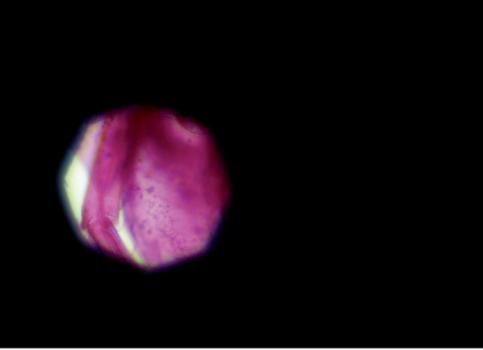

Focus Image of Field Diaphragm – While keeping the sample in focus, rotate the condenser focusing knob as illustrated to bring the edges of the field diaphragm into focus.

**Center Image of Field Diaphragm** – Insert a pair of 2 mm hex keys into the slots as illustrated and rotate to center the image of the field diaphragm.

OPTIONAL: Toggle Phase Annulus into Light Path – Use the illustrated switch to toggle appropriate condenser phase annulus into the light path. (PhL, PhI, Ph2, or Ph3).

**OPTIONAL: Center Phase Annulus** – Insert a pair of 2 mm hex keys into the illustrated slots and rotate to center the image of the condenser phase annulus (light gray ring) within the image of the fixed-position phase annulus etched into the objective (black ring). The Bertrand lens may now be removed and the system is ready for phase contrast imaging.

Sample is stained whole mount of *Daphnia magna* (water flea) imaged using a Nikon Ti2-E inverted microscope, 10x Achro ADL apodized phase contrast objective, and DS-Fi3 color CMOS camera.
